SEMICONDUCTOR INTEGRATED CIRCUIT DEVICE,

PROGRAM DELIVERY METHOD, AND PROGRAM DELIVERY SYSTEM

--RELATED APPLICATIONS

The present application is a Divisional of U.S. Application No. 10/611,879, filed on July 3, 2003, which claims priority of Japanese Patent Application No. 2002-318172 filed on October 31, 2002, the contents of which are hereby incorporated by reference.--

10   ## BACKGROUND OF THE INVENTION

The present invention relates to a semiconductor LSI having the function of decrypting an encrypted program and executing the decrypted program which is mounted on information equipment or the like. More particularly, it relates to a processing system and method for encrypting a program and delivering the encrypted program from a device

15   at a associated with a program owner to a device at a associated with a program user.

With the widespread use of information equipment capable of rewriting a program or executing a user program, a system for preventing illegal copying of software has been devised in recent years. In a method in which a program is encrypted and delivered, provision has been made to prevent the copying of a program for decrypting the encrypted

20   program (hereinafter referred to as the "decryption program". For example, a decryption program is disposed in the internal memory of an LSI from which it cannot be read from the outside and the decrypted program is further protected from being read from the outside (see, e.g., Japanese Laid-Open Patent Publication No. HEI 8-30558).

FIG. 18 is a block diagram showing a conventional semiconductor integrated

25   circuit device for executing an encrypted program.

1

The semiconductor integrated circuit device **1** shown in FIG. **18** has: a CPU **3**; internal mimories **4** and **5** for inputting/outputting data via an internal bus **7**; a bus port **6** for controlling the inputting/outputting of data to and from the outside via an external bus **2**; an I/O port **9** connected to the CPU **3** via an I/O bus **8**; a memory port **10** for controlling

5   the internal RAM **5**; and control registers **11** for controlling the memory port **10**.

A decryption program for decrypting the encrypted program is stored in the internal ROM **4**. The encrypted program is read in the internal RAM **5** and decrypted in accordance with the decryption program. The decrypted program is written in the internal RAM **5**. The decrypted program written in the internal RAM **5** is protected from being read

10   from the memory port **10** to the outside under the control of the control registers **11**.

However, since the decryption program is kept in the LSI as described above, an internal nonvolatile memory should be provided in the LSI, which increases cost required for the LSI.

In addition, if a malicious program is encrypted, read in the LSI, and then

15   executed, the decryption program may be transferred by the program to the outside and hacked. The use of the decryption program that has been hacked makes it possible to hack the encrypted program. Once the encrypted program is hacked, the LSI cannot be used any more since the decryption program cannot be changed.

A problem has also been encountered that an encryption program and an

20   encryption strength cannot be selected by the encrypted program transferor.

SUMMARY OF THE INVENTION

It is therefore an object of the present invention to provide a lower-cost semiconductor integrated circuit device which allows a reduction in the probability that an encrypted program is hacked.

25   To solve the foregoing problems, a first semiconductor integrated circuit device

2

according to the present invention comprises: a first memory for inputting and outputting data between a bus and itself; a second memory for inputting and outputting data between the bus and itself; a secret key holder for holding a secret key; a bus port for controlling access from outside to the bus; a CPU for storing an encrypted program and a decryption

5   program in the first memory via the bus port, decrypting the encrypted program by using the decryption program and the secret key, and executing the decrypted program; and a controller for causing, when the encrypted program and the decryption program are stored in the first memory, the bus port to disable access from the outside, enabling access to the first and second memories, and thereby transferring the encrypted program and the

10   decryption program from the first memory to the second memory, disabling access to the first memory when the transfer is completed, and disabling access to the second memory when the decryption and the execution of the decrypted program are completed.

With the first semiconductor integrated circuit device according to the present invention, it is no more necessary to provide the semiconductor integrated circuit device

15   with an internal nonvolatile memory for keeping the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked.

Preferably, the first semiconductor integrated circuit device according to the

20   present invention further comprises: a secret key access port for controlling access from the CPU to the secret key holder, wherein the secret key access port enables access to the secret key holder when the transfer is completed and disables access to the secrete key holder when the execution of the decrypted program is completed.

In the first semiconductor integrated circuit device according to the present

25   invention, the CPU preferably includes a register and erases data stored in the register if

the execution of the decrypted program is completed.

In the first semiconductor integrated circuit device according to the present invention, the controller preferably controls access to the first and second memories by controlling chip select signals to the first and second memories.

5 In the first semiconductor integrated circuit device according to the present invention, the controller preferably includes a flag storing portion for storing first and second flags, enables access to the first and second memories when the first flag is set, disables access to the first memory when the first flag is reset and the second flag is set, and disables access to the second memory when each of the first and second flags is reset, 10 the bus port preferably disables access from the outside when at least one of the first and second flags is set, and the CPU preferably sets the first and second flags when the encrypted program and the decryption program are inputted to the first memory, resets the first flag when the transfer is completed, and resets the second flag when the execution of the decrypted program is completed.

15 To solve the foregoing problems, a second semiconductor integrated circuit device according to the present invention comprises: a first memory for inputting and outputting data between a bus and itself; a second memory for inputting and outputting data between the bus and itself; a first memory port connected between the bus and the first memory to control access from the bus to the first memory; a second memory port connected between 20 the bus and the second memory to control access from the bus to the second memory; a secret key holder for holding a secret key; a bus port for controlling access from outside to the bus; a CPU having a register, the CPU writing an encrypted program and a decryption program in the first memory via the bus port, decrypting the encrypted program by using the decryption program and the secret key, writing the decrypted program in the second memory, and executing the decrypted program; and a controller for causing, when the

4

writing to the first memory is completed, the bus port to disable access from the outside to the bus, causing the first memory port to disable the writing to the first memory, and causing the second memory port to enable access to the second memory and causing, when the execution of the decrypted program is completed, the CPU to erase data stored in the

5 register and disable access to the secrete key holder, while causing the second memory port to disable access to the second memory.

With the second semiconductor integrated circuit device according to the present invention, it is no more necessary to provide the semiconductor integrated circuit device with an internal nonvolatile memory for keeping the decryption program so that a cost

10 reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked.

To solve the foregoing problems, a third semiconductor integrated circuit device according to the present invention comprises: a first memory for inputting and outputting

15 data between a bus and itself; a second memory for inputting and outputting data between the bus and itself; a memory port connected between the bus and the first memory to control access from the bus to the first memory; a secret key holder for holding a secret key; a bus port for controlling access from outside to the bus; a CPU having a register, the CPU writing an encrypted program and a decryption program in the first memory via the

20 bus port, decrypting the encrypted program by using the decryption program and the secret key, writing the decrypted program in the second memory, and executing the decrypted program; and a controller including a memory initializer for erasing data in the second memory, the controller causing, when the wiring to the first memory is completed, the bus port to disable access from the outside to the bus and causing the memory port to disable the writing to the first memory and causing, when the execution of the decrypted program

25 the writing to the first memory and causing, when the execution of the decrypted program

5

is completed, the CPU to erase data stored in the register and disable access to the secret

key holder and causing the memory initializer to erase the data in the second memory.

With the third semiconductor integrated circuit device according to the present

invention, it is no more necessary to provide the semiconductor integrated circuit device

5   with an internal nonvolatile memory for keeping the decryption program so that a cost

reduction is achieved. Moreover, the encrypted program can be decrypted and executed,

while the program and data under decryption are not monitored from the outside. This

reduces the probability that the encrypted program is hacked.

To solve the foregoing problems, a fourth semiconductor integrated circuit device

10   according to the present invention comprises: a first memory for inputting and outputting

data between a bus and itself; a second memory for inputting and outputting data between

the bus and itself; a secret key holder for holding a secret key; a decryption key holder for

holding a decryption key; a bus port for controlling access from outside to the bus; a CPU

including a register, the CPU performing first storage for storing the encrypted decryption

15   key and a decryption key decryption program in the first memory via the bus port,

performing first decryption for decrypting the encrypted decryption key by using the

decryption key decryption program and the secret key, writing the decrypted decryption

key in the decryption key holder, performing second storage for storing an encrypted

program and a decryption program in the first memory, performing decryption for

20   decrypting the encrypted program by using the decryption program and the decrypted

decryption key, and executing the decrypted program; and a controller for causing, when

the first storage to the first memory is completed, the bus port to disable access from the

outside to the bus and enabling access to the first and second memories such that the

encrypted decryption key and the decryption key decryption program are transferred from

25   the first memory to the second memory, enabling, when the transfer is completed, access to

6

the secret key holder and disabling access to the first memory; causing, when the first decryption is completed, the CPU to erase data stored in register and disable access to the secret key holder, while disabling access to the second memory, enabling access to the first memory, and causing the bus port to enable access from the outside to the bus, causing,

5   when the second storage to the first memory is completed, the bus port to disable access from the outside to the bus and enabling access to the second memory such that the encrypted program and the decryption program are transferred from the first memory to the second memory, enabling, when the transfer is completed, access to the decryption key holder and disabling access to the first memory, and causing, when the second decryption

10   and the execution of the decrypted program are completed, the CPU to erase data stored in the register and disable access to the secret key holder and disabling access to the second memory.

With the fourth semiconductor integrated circuit device according to the present invention, it is no more necessary to provide the semiconductor integrated circuit device

15   with an internal nonvolatile memory for keeping the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked. In addition, the encryption program and the encryption strength can be selected at the encrypted program transferor.

20   To solve the foregoing problems, a first program delivery method according to the present invention is a program delivery method for delivering a program between a first device and a second device, the method comprising the steps of: transferring a public key from the second device to the first device; transferring a decryption program to the second device from the outside thereof; encrypting the program by using the public key in the first

25   device and transferring the encrypted program to the second device; and decrypting the

7

encrypted program by using a secret key corresponding to the public key and the decryption program in the second device.

In accordance with the first program delivery method of the present invention, it is no more necessary to provide the semiconductor integrated circuit device with an internal

5   nonvolatile memory for keeping the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked.

To solve the foregoing problems, a second program delivery method according to

10   the present invention is a program delivery method for delivering a program between a first device and a second device, the method comprising the steps of: transferring a public key from the second device to the first device; encrypting a decryption key by using the public key in the first device and transferring the encrypted decryption key to the second device; decrypting the encrypted decryption key by using a secret key corresponding to the public

15   key in the second device; encrypting the program by using an encryption key corresponding to the decryption key in the first device and transferring the encrypted program to the second device; and decrypting the encrypted program by using the decrypted decryption key in the second device.

In accordance with the second program delivery method of the present invention,

20   it is no more necessary to provide the semiconductor integrated circuit device with an internal nonvolatile memory for keeping the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked. In addition, the encryption program and

25   the encryption strength can be selected at the encrypted program transferor.

8

To solve the foregoing problems, a first program delivery system according to the present invention is a program delivery system for delivering a program, the system comprising: a first device and a second device, the first device encrypting the program by using a public key and transferring the encrypted program to the second device and the

5   second device decrypting the program encrypted by the first device by using a secret key corresponding to the public key and a decryption program transferred from the outside of the second device.

In accordance with the first program delivery system of the present invention, it is no more necessary to provide the semiconductor integrated circuit device with an internal

10   nonvolatile memory for keeping the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked.

To solve the foregoing problems, a second program delivery system according to

15   the present invention is a program delivery system for delivering a program, the system comprising: a first device and a second device, the first device encrypting a decryption key by using a public key, transferring the encrypted decryption key to the second device, encrypting the program by using an encryption key corresponding to the decryption key, and transferring the encrypted program to the second device, the second device decrypting

20   the decryption key encrypted by the first device by using a secret key corresponding to the public key and decrypting the program encrypted by the first device by using the decrypted decryption key.

In accordance with the second program delivery system of the present invention, it is no more necessary to provide the semiconductor integrated circuit device with an

25   internal nonvolatile memory for keeping the decryption program so that a cost reduction is

9

achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked. In addition, the encryption program and the encryption strength can be selected at the encrypted program transferor.

10   **DETAILED DESCRIPTION OF THE INVENTION**

Referring to the drawings, the individual embodiments of the present invention will be described herein below.

EMBODIMENT 1

FIG. 1 is a block diagram for illustrating a structure of a semiconductor integrated

15   circuit device 101 in a first embodiment of the present invention.

As shown in FIG. 1, an encrypted program is transferred from a PC 128a (corresponding to a first device) which is a device at a program developer to a program user via a PC 126. In the semiconductor integrated circuit device 101 (corresponding to a second device) within information equipment 140 at the user, the encrypted program is

20   decrypted by using a secret key and a decryption program.

The PC 128a is a device at the program developer and keeps a program D128a and an encryption program 128b for encrypting a program.

The information equipment 140 is equipment at the program user and has: the semiconductor integrated circuit device 101; a flash memory 123a for keeping a decryption

25   program D123a; a USB upstream port 124; and peripheral equipment 150. An outer bus

11

102 provides connection among the semiconductor integrated circuit 101, the flash memory 123a, and the USB upstream port 124.

The semiconductor integrated circuit device has: a CPU 103a; internal RAMs 104 (corresponding to a first memory) and 105 (corresponding to a second memory); a public

5   key storing register 106; a bus port 110a; a security controller 111a; and an I/O port 122. The internal bus 109 is connected in the manner as shown in the drawing.

The CPU 103a has a general-purpose register controller 119a and general-purpose registers 120a.

The security controller 111a has a flag storing portion 113a for storing a program

10   decryption execute flag 112F (corresponding to a second flag) and a RAM copy flag 113F (corresponding to a first flag) , a chip select dispatcher 114a, and a DMA controller 118a.

A specific description will be given to the respective contents and operations of the individual elements.

The external bus 102 is used to transfer a public key stored in the public key

15   storing register 106 to the personal computer 128a and transfer a program encrypted by using the public key and the encryption program D128b to the semiconductor integrated circuit device 101.

The CPU 103a operates in accordance with a program stored in the internal RAMs 104 and 105 or in the flash memory 123a. The CPU 103a not only operates a

20   normal program but also decrypts an encrypted program and executes the decrypted program. The CPU 103a also transfers the encrypted program inputted from the outside and the decryption program D123a to the internal RAM 104.

The internal RAM 104 is a memory used during a normal operation, i.e., when either of the decryption program D123a and the decrypted program is not executed. A

25   description will be given to the case where a program encrypted by using the public key

12

and the encryption program **D128b** is decrypted and executed. First, the encrypted program and the decryption program **D123a** in the flash memory **123a** are transferred by the CPU **103a** to the internal RAM **104** in the state in which the external bus **102** and the internal bus **109** are connected to each other by the bus port **110a**. Then, after the bus port **110a**

5   disconnects the external bus **102** and the internal bus **109** from each other, the encrypted program and the decryption program **D123a** are transferred by the DMA controller **118a** from the internal RAM **104** to the internal RAM **105**. Thereafter, the security controller **111a** disables access from the internal bus **109** to the internal RAM **104** until the execution of the decrypted program is completed.

10   The internal RAM **105** is used during the execution of the decryption program **D123a** and during the execution of the decrypted program. A description will be given to the case where the encrypted program is decrypted and executed. After the bus port **110a** disconnects the external bus **102** and the internal bus **109** from each other, the encrypted program and the decryption program **D123a** are transferred by the DMA controller **118a**

15   from the internal RAM **104** to the internal RAM **105**. In the state in which the external bus **102** and the internal bus **109** are connected to each other by the bus port **110a**, the security controller **111a** disables access from the internal bus **109** to the internal RAM **105**. Accordingly, the decrypted program temporarily stored in the internal RAM **105** and data during the execution of a decryption process are not monitored from the outside.

20   The public key storing register **106** is a register storing therein a public key, which is used only for reading. The public key is transferred to the personal computer **128a** disposed outside the semiconductor integrated circuit device **101** and used when the program **D128a** is encrypted in accordance with the encryption program **D128b**.

The secret key storing register **107** is a register storing therein a secret key, which

25   is used only for reading. The secret key is used when the encrypted program is decrypted in

accordance with the decryption program **D123a**.

The secret key access port **108a** enables the CPU **103a** to read the secrete key from the secret key storing register **107** only while the RAM copy flag **113F** is reset. Specifically, the secret key access port **108a** enables the CPU **103a** to read the secret key

5   from the secret key storing register **107** only while the program is decrypted, the decrypted program is executed after the decryption program **D123a** is initiated, the transfer of the encrypted program and the decryption program **D123a** from the internal RAM **104** to the internal RAM **105** is completed, and the RAM copy flag **113F** is reset. At any time other than the above, the secret key access port **108a** disables the reading of the secret key.

10   The internal bus **109** is used to transfer a program and data within the semiconductor integrated circuit device **101**.

The bus port **110a** disconnects the internal bus **109** and the external bus **102** from each other if at least one of the program decryption execute flag **112F** and the RAM copy flag **113F** is set. Accordingly, the internal bus **109** and the internal RAM **105** are not

15   monitored from the outside during the transfer of the encrypted program and the decryption program **D123a** and during the execution of the decryption program **D123a** and the decrypted program. In any case other than the above, the internal bus **109** and the external bus **102** are connected to each other.

The security controller **111a** is internally provided with the flag storing portion

20   **113a** for keeping the program decryption execute flag **112F** and the RAM copy flag **113F**, with the chip select dispatcher **114a**, and with the DMA controller **118**. The security controller **111a** controls the bus port **110a**, the secret key access port **108a**, chip select signals **116S** and **117S**, and the general-purpose register controller **119a** in decrypting the program encrypted by using the encryption program **D128b** and the public key stored in

25   the public key storing register **106** and executing the decrypted program.

14

A description will be given to the case where the program encrypted by the encryption program **D128b** is decrypted and executed. First, when the encrypted program and the decryption program **D123a** are transferred by the CPU **103a** to the internal RAM **104** in the state in which the external bus **102** and the internal bus **109** are connected to

5   each other by the bus port **110a**, the bus port **110a** then disconnects the external bus **102** and the internal bus **109** from each other. Then, the chip select dispatcher **114a** asserts the chip select signals **116S** and **117S** such that the program encrypted by the DMA controller **118a** and the decryption program **D123a** are transferred from the internal RAM **104** to the internal RAM **105**. When the transfer is completed, the chip select dispatcher **114a** negates

10   the chip select signal **116S** and then shifts to the control of the CPU **103a**. When the program is decrypted in the CPU **103a** and the execution of the decrypted program is completed, a completion notice is given to the chip select dispatcher **114a**. Upon receipt of the notice, the chip select dispatcher **114a** generates the chip select signal **117S**, causes the general-purpose register controller **119a** to initialize the general-purpose registers **120a**,

15   and outputs the chip select signal **115S** from the CPU **103a** as the chip select signal **116S**. Thereafter, the bus port **110a** connects the internal bus **109** and the external bus **102** to each other.

The program decryption execute flag **112F** is set by the CPU **103a** at the initiation of the decryption program **D123a** and reset by the CPU **103a** at the completion of the

20   execution of the decrypted program. The decryption program **D123a** is initiated, the transfer of the encrypted program and the decryption program **D123a** from the internal RAM **104** to the internal RAM **105** is completed, and the RAM copy flag **113F** is reset. While the encrypted program is decrypted and the decrypted program is executed thereafter, access to the internal RAM **104** is disabled, while access to the internal RAM **105** and to

25   the secret key storing register **107** is enabled. When the program decryption execute flag

15

112F is reset, access to the internal RAM 105 and to the secret key storing register 107 is disabled.

The RAM copy flag 113F is set by the CPU 103a at the initiation of the decryption program D123a and reset at the completion of data transfer from the internal

5   RAM 104 to the internal RAM 105. Since the internal RAMs 104 and 105 are at the same location on a memory map, the respective chip select signals to the internal RAMs 104 and 105 are not normally asserted simultaneously. However, each of the chip select signals 116S and 117S from the chip select dispatcher 114a to the internal RAMs 104 and 105 is asserted by setting the RAM copy flag 113F when the encrypted program or the like is to

10   be transferred from the internal RAM 104 to the internal RAM 105.

The chip select dispatcher (hereinafter referred to as "CS dispatcher") 114a asserts each of the chip select signals 116S and 117S when the RAM copy flag 113F is set, thereby enabling the DMA controller 118a to transfer the encrypted program and the decryption program D123a from the internal RAM 104 to the internal RAM 105. When the program

15   decryption execute flag 112F is set and the RAM copy flag 113F is reset, the CS dispatcher 114a negates the chip select signal 116S and transfers the chip select signal 115S as the chip select signal 117S. This enables access to the internal RAM 105 during the decryption of the encrypted program and during the execution of the decrypted program. In any case other than those mentioned above, the CS dispatcher 114a transfers the chip select signal

20   115S as the chip select signal 116S and negates the chip select signal 117S, thereby disabling access to the internal RAM 105 during a normal operation, i.e., when either of the decryption program D123a and the decrypted program is not executed.

The chip select signal 115S is outputted from the CPU 103a and asserted when the internal RAM 104 or the internal RAM 105 is to be accessed.

25   The chip select signals 116S and 117S are outputted from the CS dispatcher 114a.

16

The chip select signal **116S** is asserted when the internal RAM **104** is to be accessed. The chip select signal **117S** is asserted when the internal RAM **105** is to be accessed.

When the RAM copy flag **113F** is set, the DMA controller **118a** transfers the encrypted program and the decryption program **D123a** from the internal RAM **104** to the internal RAM **105**. When the transfer is completed, the RAM copy flag **113** is reset.

The general-purpose register controller **119a** resets the general-purpose registers **120a** when the program decryption execute flag **112F** is reset. During the decryption of the encrypted program, therefore, data generated in the general-purpose registers **120a** during the execution of the decrypted program is not monitored from the outside.

The I/O port **122** is connected to the CPU **103a** via the I/O bus **121**. The I/O port **122** is also connected to an external circuit such as a sound module **151** or a video module **152** in the peripheral equipment **150**.

The flash memory **123a** keeps the decryption program **D123a**.

The decryption program **D123a** is transferred to the internal RAM **105** via the internal RAM **104** within the semiconductor integrated circuit device **101** and used in conjunction with the secret key stored in the secret key storing register **107** when the encrypted program is decrypted.

The USB upstream port **124** is connected to the personal computer **126** via a USB cable **125** and used to transfer the encrypted program to the semiconductor integrated circuit device **101**.

The USB cable **125** is used to transfer the encrypted program from the personal computer **126** to the USB upstream port **124**.

The personal computer **126** receives the encrypted program from the personal computer **128a** and transfers the encrypted program to the information equipment **140** on which the semiconductor integrated circuit device **101** is mounted.

17

A network line **127** is used to transfer the encrypted program from the personal computer **128** to the personal computer **126**.

The personal computer **128** receives the public key stored in the public key storing register **106** from the personal computer **126** via the network line **127**, encrypts the

5 program **D128a** by using the encryption program **D128b** and the public key, and transfers the encrypted program to the personal computer **126** via the network line **127**.

The program **128a** is encrypted by using the encryption program **D128b** and the public key stored in the public key storing register **106** and then transferred to the semiconductor integrated circuit device **101** via the network line **127**, the personal

10 computer **126**, the USB cable **125**, the USB upstream port **124**, and the external bus **102**. The encrypted program **128a** is decrypted in the semiconductor integrated circuit device **101** by using the decryption program **D123a** and the secret key stored in the secret key storing register **107**.

A reference numeral **D128b** denotes an encryption program for encrypting the

15 program **D128a** by using the public key stored in the public key storing register **106**.

The information equipment **140** has: the semiconductor integrated circuit device **101**; the peripheral equipment **150**; the flash memory **123a**; and the USB upstream port **124**.

The peripheral equipment **150** has: the sound module **151**; and the video module

20 **152** and is connected to the I/O port **122** in the semiconductor integrated circuit device **101**.

The sound module **151** is connected to the I/O port **122** of the semiconductor integrated circuit device **101** to perform reproduction, recording, and the like of a sound through the transmission and reception of transferred data and the reception of a control signal.

25 The video module **152** is connected to the I/O port **122** of the semiconductor

integrated circuit device **101** to perform reproduction of a dynamic picture image through the transmission and reception of transferred data and the reception of a control signal.

Referring to FIG. **2**, the outline of the procedure of decrypting the encrypted program to generate the program **D128a** and executing the program **D128a** will be

5 described.

FIG. **2** is a flow chart showing the procedure of decrypting the encrypted program in the first embodiment.

First, in Step ST201, the CPU **103a** transfers the decryption program **D123a** and the encrypted program to the internal RAM **104**.

10 When the transfer is completed, the whole process then advances to Step ST202 where the CPU **103a** sets the program decryption execute flag **112F** and the RAM copy flag **113F**. At this time, the bus port **110a** disconnects the internal bus **109** and the external bus **102** from each other.

After the disconnection, the whole process then advances to Step ST203 where the

15 DMA controller **118a** transfers the decryption program **D123a** and the encrypted program in the internal RAM **104** to the internal RAM **105**.

When the transfer is completed, the whole process then advances to Step ST204 where the CPU **103a** resets the RAM copy flag **113F**. From the resetting of the RAM copy flag **113F** on till the completion of Step ST206, which will be described later, the CS

20 dispatcher **114a** does not assert the chip select signal **116S**.

The whole process then advances to Step ST205 where the CPU **103a** executes the decryption program **D123a**, decrypts the encrypted program by using the secret key stored in the secret key storing register **107** to generate the program **D128a**, and writes the generated program **D128a** in the internal RAM **105**.

25 The whole process then advances to Step ST206 where the CPU **103a** executes

19

the program **D128a**.

Finally, the whole process advances to Step ST207 where the CPU **103a** resets the program decryption execute flag **112F**. When the program decryption execute flag **112F** is reset, the general-purpose register controller **119a** resets the general-purpose registers **120a**.

5   When the program decryption execute flag **112a** is reset, the bus port **110a** connects the internal bus **109** and the external bus **102** to each other, while the CS dispatcher **114a** outputs the chip select signal **116S** as the chip select signal **115S** and negates the chip select signal **117S**.

Since the chip select signal **116S** is not asserted while the decryption program

10   **D123a** is executed and the program **D128a** is generated, the data and program **D128a** under decryption are not stored in the internal RAM **104**. Since the chip select signal **117S** is negated while the external bus **102** and the internal bus **109** are connected to each other by the bus port **110a**, the data and program **D128a** under decryption is prevented from being monitored from the outside.

15   Thus, according to the first embodiment, it is no more necessary to provide the semiconductor integrated circuit device with an internal nonvolatile memory for keeping the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is

20   hacked.

EMBODIMENT 2

FIG. 3 is a block diagram showing a structure of a semiconductor integrated circuit device **301** according to a second embodiment of the present invention.

A semiconductor integrated circuit **301** shown in FIG. 3 is different from the

25   semiconductor integrated circuit device **101** shown in FIG. 1 in that it further comprises a

20

memory port **302** (corresponding to a first memory port) and a memory port **303**

(corresponding to a second memory port). The semiconductor integrated circuit device **301**

is also different from the semiconductor integrated circuit device **101** in that a security

controller **111b** has only a flag storing portion **113b** for storing the program decryption

5   execute flag **112F**. As for the other components, they operate similarly to the components

shown in FIG. 1 so that the description thereof will not be repeated.

The memory port **302** halts writing to the internal RAM **104** under the control of

the security controller when the program decryption execute flag **112F** is set. In other

words, data cannot be written in the internal RAM **104** during the decryption of the

10   program and during the execution of the decrypted program.

The memory port **303** halts access to the internal RAM **105** under the control of

the security controller **111b** when the program decryption execute flag **112F** is reset. In

other words, the internal RAM **105** cannot be accessed during the internal bus **109** and the

external bus **102** are connected to each other by a bus port **110b**. Accordingly, the

15   decrypted program and data during the execution of a decryption process, which are

written in the internal RAM **105**, are not monitored from the outside.

A description will be given next to the procedure of decrypting the encrypted

program to generate the program **D128a** and executing the program **D128a**.

FIG. 4 is a flow chart showing the procedure of decrypting the encrypted program

20   in the second embodiment.

First, in Step ST201, a CPU **103b** transfers the decryption program **D123a** and the

encrypted program to the internal RAM **104**.

When the transfer is completed, the whole process then advances to ST402 where

the CPU **103b** sets the program decryption execute flag **112F**. At this time, the bus port

25   **110b** disconnects the internal bus **109** and the external bus **102** from each other. The

21

memory port **302** halts writing to the internal RAM **104**, while the memory port **303** enables access to the internal RAM **105**.

Then, the whole process advances to Step ST205 where the CPU **103b** executes the decryption program **D123a**, thereby decrypts the encrypted program by using the secret

5   key stored in the secrete key storing register **107** to generate the program **D128a**, and writes the generated program **D128a** in the internal RAM **105**.

Then, the whole process advances to Step ST206 where the CPU **103b** executes the program **D128a**.

Finally, when the execution of the program **D128a** is completed, the whole

10   process advances to Step ST207 where the program decryption execute flag **112F** is reset. When the program decryption execute flag **112F** is reset, the general-purpose register controller **119b** resets the general-purpose registers **120b** under the control of the security controller **111b**. When the program decryption execute flag **112F** is reset, the bus port **110b** connects the internal bus **109** and the external bus **102** to each other, while the memory

15   port **302** enables writing to the internal RAM **104** and the memory port **303** halts access to the internal RAM **105**.

In the semiconductor integrated circuit device **301**, the memory port **302** executes the decryption program **D123a** and halts writing to the internal RAM **104** while the program **D128a** is generated so that the data and program **D128a** under decryption are not

20   stored in the internal RAM **104**. In addition, the memory port **303** halts access to the internal RAM **105** while the external bus **102** and the internal bus **109** are connected to each other by the bus port **110b** so that the data and program **D128a** under decryption are not outputted to the outside.

Thus, according to the second embodiment, it is no more necessary to provide the

25   semiconductor integrated circuit device with an internal nonvolatile memory for keeping

22

the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked.

5   EMBODIMENT 3

FIG. 5 is a block diagram showing a structure of a semiconductor integrated circuit device **501** according to a third embodiment of the present invention.

A semiconductor integrated circuit device **501** shown in FIG. 5 is different from the semiconductor integrated circuit device **101** shown in FIG. 1 in that it further comprises

10   a memory port **402**. The semiconductor integrated circuit device **501** is also different from the semiconductor integrated circuit device **101** shown in FIG. 1 in that a security controller **111c** has a flag storing portion **113c** for storing the program decryption execute flag **112F** and a RAM initializer **502** (corresponding to a memory initializer). As for the other components, they operate similarly to the components shown in FIG. 1 so that the

15   description thereof will not be repeated.

Immediately before the program decryption execute flag **112F** is reset, the RAM initializer **502** writes "1" in each of the regions of the internal RAM **105** to erase data, thereby preventing the decrypted program and the data under decryption, which are written in the internal RAM **105,** from being monitored from the outside.

20   A description will be given next to the procedure of decrypting the encrypted program to generate the program **D128a** and executing the program **D128a**.

FIG. 6 is a flow chart showing the procedure of decrypting the encrypted program in the third embodiment.

First, in Step ST201, a CPU **103c** transfers the decryption program **D123a** and the

25   encrypted program to the internal RAM **104**.

23

When the transfer is completed, the whole process then advances to ST402 where the CPU **103c** sets the program decryption execute flag **112F**. At this time, a bus port **110c** disconnects the internal bus **109** and the external bus **102** from each other, while the memory port **402** halts writing to the internal RAM **104** under the control of the security

5   controller **111c**.

Then, the whole process advances to Step ST205 where the CPU **103c** executes the decryption program **D123a**, thereby decrypts the encrypted program by using the secret key stored in the secrete key storing register **107** to generate the program **D128a**, and writes the generated program **D128a** in the internal RAM **105**.

10   When the generated program **D128a** is written in the internal RAM **105**, the whole process then advances to Step ST206 where the CPU **103c** executes the program **D128a**.

The whole process then advances to Step ST607 where the RAM initializer **502** writes "1" in each of the regions of the internal RAM **105** to erase data.

15   Finally, when the data in the internal RAM **105** is erased, the whole process advances to Step ST207 where the program decryption execute flag **112F** is reset. When the program decryption execute flag **112F** is reset, the general-purpose register controller **119c** resets the general-purpose registers **120c** under the control of the security controller **111b**. When the program decryption execute flag **112F** is reset, the bus port **110c** connects

20   the internal bus **109** and the external bus **102** to each other, while the memory port **402** enables writing to the internal RAM **104** under the control of the security controller **111c**.

In the semiconductor integrated circuit device **501**, the memory port **402** executes the decryption program **D123a** and halts writing to the internal RAM **104** whi le the program **D128a** is generated so that the data and program **D128a** under decryption are not

25   stored in the internal RAM **104**. In addition, the RAM initializer **502** has completely erased

data in the internal RAM **105** immediately before the bus port **110c** brings the external bus **102** and the internal bus **109** in the disconnected state into the connected state so that the data and program **D128a** under decryption are not outputted to the outside.

Thus, according to the third embodiment, it is no more necessary to provide the

5   semiconductor integrated circuit device with an internal nonvolatile memory for keeping the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked.

10   EMBODIMENT 4

FIG. 7 is a block diagram showing a structure of a semiconductor integrated circuit device **701** according to a fourth embodiment of the present invention.

A semiconductor integrated circuit device **701** shown in FIG. 7 is different from the semiconductor integrated circuit device **101** shown in FIG. 1 in that it further comprises

15   a decryption key access port **703** and a decryption key storing register **702**. A PC **128d** is different from the PC **128a** shown in FIG. 1 in that it keeps a decryption key encryption program **D728c**, an encryption key **D728d**, and a decryption key **D728e** in addition to the program **D728a** and the encryption program **D728b**. A flag storing portion **113d** is different from the flag storing portion **113a** shown in FIG. 1 in that it keeps a decryption key

20   decryption flag **704F** in addition to the program decryption execute flag **112F** and the RAM copy flag **113F**. A flash memory **123d** is different from the flash memory **123a** in that it keeps a decryption key decryption program **D723b** in addition to the decryption program **723a**. As for the other components, they operate similarly to the components shown in FIG. 1 so that a description will be given with particular emphasis on different

25   portions between FIGS. 7 and 1.

A CPU **103d** operates in accordance with a program stored in the internal RAM

104 or **105** or in the flash memory **123d**. Besides operating a normal program, the CPU

103d executes the decryption of the encrypted decryption key and the decryption of the

encrypted program as well as the decrypted program. The CPU **103d** also transfers the

5   encrypted decryption key inputted from the outside, the encrypted program, the decryption

key encryption program **D723b**, and the decryption program **D723a** to the internal RAM

104.

The internal RAM **104** is a memory used during a normal operation, i.e., when

none of the decryption program **D723a**, the decryption key decryption program **D723b**,

10   and the decrypted program is executed. A description will be given to the case where the

encrypted decryption key is decrypted and stored in the decryption key storing register **702**.

First, in the state in which the external bus **102** and the internal bus **109** are connected to

each other by the bus port **110d**, the CPU **103d** transfers the encrypted decryption key and

the decryption key decryption program **D723b** in the flash memory **123d** to the internal

15   RAM **104** via the external bus **102** and the internal bus **109**. Then, after the bus port **110d**

disconnects the external bus **102** and the internal bus **109** from each other, a DMA

controller **118d** transfers the encrypted decryption key and the decryption key decryption

program **D723b** from the internal RAM **104** to the internal RAM **105**. Thereafter, a

security controller **111d** disables access from the internal bus **109** to the internal RAM **104**

20   until the decryption key decryption program **D723b** is completed.

Subsequently, a description will be given to the case where the encrypted program

is decrypted and executed. First, the CPU **103d** transfers the encrypted program and the

decryption program **D723a** to the internal RAM **104** in the state in which the external bus

102 and the internal bus **109** are connected to each other by the bus port **110d**. After the

25   bus port **110d** then disconnects the external bus **102** and the internal bus **109** from each

26

other, the DMA controller **118d** transfers the encrypted program and the decryption program **D723a** from the internal RAM **104** to the internal RAM **105**. Thereafter, the security controller **111d** disables access from the internal bus **109** to the internal RAM **104** until the execution of the decrypted program is completed.

5   The internal RAM **105** is used during the execution of the decryption key decryption program **D723b**, the decryption program **D723a**, and the decrypted program **D728b**. A description will be given to the case where the encrypted decryption key is decrypted and stored in the decryption key storing register **702**. After the bus port **110d** disconnects the external bus **102** and the internal bus **109** from each other, the DMA

10   controller **118d** transfers the encrypted decryption key and the decryption key decryption program **D723b** from the internal RAM **104** to the internal RAM **105**. During the decryption of the encrypted decryption key, the CPU **103d** decrypts the encrypted decryption key by using the internal RAM **105**. A description will be given to the case where the encrypted program is decrypted and executed. After the bus port **110d**

15   disconnects the external bus **102** and the internal bus **109** from each other, the encrypted program and the decryption program **D723a** are transferred from the internal RAM **104** to the internal RAM **105**. During the decryption of the encrypted program and during the execution of the decrypted program, the CPU **103d** decrypts the encrypted program and executes the decrypted program by using the internal RAM **105**. While the external bus

20   **102** and the internal bus **109** are connected to each other by the bus port **110d**, access from the internal bus **109** to the internal RAM **105** is disabled. Accordingly, the decrypted decryption key **D728e**, the decrypted program **D728a**, and data during the execution of these decryption processes, each temporarily stored in the internal RAM **105**, are not monitored from the outside.

25   The public key storing register **106** is a register storing a public key, which is used

27

only for reading. The public key is transferred to the personal computer **128e** disposed outside the semiconductor integrated circuit device **701** and used in conjunction with the decryption key encryption program **D728c** to encrypt the decryption key **D728e**. The encrypted decryption key is decrypted by using the decryption key decryption program

5   **D723b** and the secret key stored in the secret key storing register **107**.

The secret key storing register **107** is a register storing a secret key, which is used only for reading. The secret key is used when the encrypted decryption key is decrypted by using the secret key.

The decryption key storing register **702** is a register for storing the decryption key

10   **D728e** such that it is written therein and read therefrom. The decryption key **D728e** is used in conjunction with the decryption key decryption program **D723b** to decrypt the encrypted program.

The secret key access port **108d** enables the CPU **103d** to read the secret key from the secret key storing register **107** only while the decryption key decryption flag **704F** is

15   set and the RAM copy flag **113F** is reset. Specifically, the CPU **103d** enables the reading of the secret key from the secret key storing register **107** only while the decryption key decryption program **D723b** is initiated, the transfer of the encrypted decryption key and the decryption key decryption program **D723b** from the internal RAM **104** to the internal RAM **105** is completed, the RAM copy flag **113F** is reset, and the encrypted decryption

20   key is decrypted thereafter. At any time other than the above, the reading of the secret key is disabled.

The decryption key access port **703** enables the writing of the decryption key **D728e** while the decryption key decryption flag **704F** is set and the RAM copy flag **113** is reset. The decryption key access port **703** enables the reading of the decryption key **D728e**

25   while the program decryption execute flag **112F** is set and the RAM copy flag **113F** is reset.

28

At any time other than the above, the writing and reading of the decryption key **D728e** are both disabled. Specifically, the writing of the decryption key **D728e** is enabled while the decryption key decryption program **D723b** is initiated, the transfer of the encrypted decryption key and the decryption key decryption program **D723b** from the internal RAM

5   **104** to the internal RAM **105** is completed, the RAM copy flag **113F** is reset, and the encrypted decryption key is decrypted thereafter. On the other hand, the reading of the decryption key **D728e** is enabled while the decryption program **D723a** is initiated, the transfer of the encrypted program and the decryption program **D723a** from the internal RAM **104** to the internal RAM **105** is completed, the RAM copy flag **113F** is reset, and the

10   encrypted program is decrypted thereafter.

The bus port **110d** disconnects the internal bus **109** and the external bus **102** from each other when at least one of the decryption key decryption flag **704F**, the program decryption execute flag **112F**, and the RAM copy flag **113F** is set. During the execution of the decryption key decryption program **D723b**, the decryption program **D723a**, and the

15   decrypted program **D728a**, therefore, the internal bus **109** and the internal bus RAM **105** are not monitored from the outside. In any case other than the above, the internal bus **109** and the external bus **102** are connected to each other.

The security controller **111d** is internally provided with a flag storing portion for keeping the decryption key decryption flag **704F**, with the program decryption execute flag

20   **112F**, and with the RAM copy flag **113F**, a CS dispatcher **114d**, and the DMA controller **118d**.

The decryption key decryption flag **704F** is set by the CPU **103** when the decryption key decryption program **D723b** is initiated and reset by the CPU **103** when the decryption of the decryption key is completed. The decryption key decryption program

25   **D723b** is initiated, the transfer of the encrypted decryption key and the decryption key

29

decryption program **D723b** from the internal RAM **104** to the internal RAM **105** is completed, and the RAM copy flag **113F** is reset. Thereafter, access to the internal RAM **104** is disabled during the decryption of the encrypted decryption key, while access to the internal RAM **105**, to the secret key storing register **107**, and to the decryption key storing register **702** is enabled. When the decryption key decryption flag **704F** is reset, access to the internal RAM **105**, to the secret key storing register **107**, and to the decryption key storing register **702** is disabled.

The program decryption execute flag **112F** is set by the CPU **103d** at the initiation of the decryption program **D723a** and reset by the CPU **103d** at the completion of the execution of the decrypted program. The decryption program **D723a** is initiated, the transfer of the encrypted program and the decryption program **D723a** from the internal RAM **104** to the internal RAM **105** is completed, and the RAM copy flag **113F** is reset. While the encrypted program is decrypted and the decrypted program is executed thereafter, access to the internal RAM **104** is disabled and access to the internal RAM **105** and to the decryption key storing register **702** is enabled. When the program decryption execute flag **112F** is reset, access to the internal RAM **105**, to the secret key storing register **107**, and to the decryption key storing register **702** is disabled.

The RAM copy flag **113F** is set by the CPU **103d** at the initiation of the decryption key decryption program **D723b** or the decryption program **D723a** and reset by the CPU **103d** at the completion of data transfer from the internal RAM **104** to the internal RAM **105**.

The CS dispatcher **114d** asserts each of the chip select signals **116S** and **117S** when the RAM copy flag **113F** is set, thereby enabling the DMA controller **118d** to transfer the encrypted decryption key, the decryption key decryption program **D723b**, the encrypted program, and the decryption program **D723a** from the internal RAM **104** to the

30

internal RAM **105**. When the decryption key decryption flag **704F** or the program

decryption execute flag **112F** is set and the RAM copy flag **113F** is reset, the CS dispatcher

114d negates the chip select signal **116S** and transfers the chip select signal **115S** as the

chip select signal **117S**. This enables access to the internal RAM **105** during the decryption

5   of the encrypted decryption key, during the decryption of the encrypted program, and

during the execution of the decrypted program. In any case other than those mentioned

above, the CS dispatcher **114d** transfers the chip select signal **115S** as the chip select signal

116S and negates the chip select signal **117S**, thereby disabling access to the internal RAM

105 during a normal operation, i.e., when none of the decryption key decryption program

10   **D723b**, the decryption program **D723a**, and the decrypted program **D728a** is executed.

When the RAM copy flag **113F** is set, the DMA controller **118d** transfers the

encrypted decryption key, the decryption key decryption program **D723b**, the encrypted

program, and the decryption program **D723a** from the internal RAM **104** to the internal

RAM **105**. When the transfer is completed, the DMA controller **118d** resets the RAM copy

15   flag **113F**.

The general-purpose register controller **119d** resets the general-purpose registers

120d when the decryption key decryption flag **704F** or the program decryption execute

flag **112F** is reset. During the decryption of the encrypted program, therefore, data

generated in the general-purpose registers **120d** during the execution of the decrypted

20   program is not monitored from the outside.

The decryption key decryption program **D723b** is kept in the flash memory **123d**.

When the decryption key encrypted by using the decryption key encryption program

D728c and the secret key is decrypted, the decryption key decryption program **D723b** is

transferred to the internal RAM **105** via the internal RAM **104** in the semiconductor

25   integrated circuit device **701** to decrypt the encrypted decryption key in conjunction with

the secret key stored in the secret key storing register **107**.

The decryption program **D723a** is kept in the flash memory **123d**. When the program encrypted by using the encryption program **D728b** and the encryption key **D728d** is decrypted, the decryption program **D723a** is transferred to the internal RAM **105** via the

5   internal RAM **104** in the semiconductor integrated circuit device **701** to decrypt the encrypted program in conjunction with the decryption key stored in the decryption key storing register **702**.

The program **D728a** is encrypted by using the encryption program **D728b** and the encryption key **D728d** and transferred to the semiconductor integrated circuit device **701**

10   via the network **127**, the personal computer **126**, the USB cable **125**, the USB upstream port **124**, and the external bus **102**. In the semiconductor integrated circuit device **701**, the program **D728a** is decrypted by using the decryption program **D723a** and the decryption key **D728e** stored in the decryption key storing register **107**.

The encryption program **D728b** is for encrypting the program **D728a** by using the

15   encryption key **D728d**.

The decryption key encryption program **D728c** is for encrypting the decryption key **D728e** in conjunction with the public key stored in the public key storing register **106**.

The encryption key **D728d** is for encrypting the program **D728a** in conjunction with the encryption program **D728b**.

20   The decryption key **D728e** is for decrypting the encrypted program by using the encryption key **D728d** in conjunction with the decryption program **D723a**.

Information equipment **740** has the semiconductor integrated circuit device **701**, the peripheral equipment **150**, the flash memory **123d**, and the USB upstream port **124**.

A description will be given next to the procedure of decrypting the encrypted

25   decryption key and storing the decryption key **D728e** in the decryption key storing register

32

702.

FIG. 8 is a flow chart showing the procedure of decrypting the encrypted decryption key in the fourth embodiment.

First, in Step ST801, the CPU **103d** transfers the decryption key decryption program **D723b** and the encrypted decryption key to the internal RAM **104**.

When the transfer is completed, the whole process then advances to Step ST802 where the CPU **103d** sets the decryption key decryption flag **704F** and the RAM copy flag **113F**. At this time, the bus port **110d** disconnects the internal bus **109** and the external bus **102** from each other.

After the disconnection, the whole process then advances to Step ST803 where the DMA controller **118d** transfers the decryption key decryption program **D723b** and the encrypted decryption key in the internal RAM **104** to the internal RAM **105**.

When the transfer is completed, the whole process then advances to Step ST804 where the CPU **103d** resets the RAM copy flag **113F**. From the resetting of the RAM copy flag **113F** on till the completion of Step ST805, which will be described later, the CS dispatcher **114d** does not assert the chip select signal **116S**.

Next, the whole process advances to Step ST805 where the CPU **103d** executes the decryption key decryption program **D723b** by using the secret key stored in the secret key storing register **107** to decrypt the encrypted decryption key, thereby generates the decryption key **D728e**, and stores it in the decryption key storing register **702**.

Finally, the whole process advances to Step ST806 where the decryption key decryption flag **704F** is reset. When the decryption key decryption flag **704F** is reset, the general-purpose register controller **119d** resets the general-purpose registers **120d**. When the decryption key decryption flag **704F** is reset, the bus port **110d** connects the internal bus **109** and the external bus **102** to each other. The CS dispatcher **114d** transfers the chip

select signal **115S** as the chip select signal **116S** and negates the chip select signal **117S**.

FIG. **9** shows the respective states of the decryption key decryption flag **704F**, the program decryption execute flag **112F**, the bus port **110d** corresponding to the state of the RAM copy flag **113F**, the secret key access port **108d**, the decryption key access port **703**,

5   and the chip select signals **116S** and **117S**.

In FIG. **9**, "Open" represents the case where the bus port **110d**, the secret key access port **108d**, and the decryption key access port **703** enable data transfer and "Close" represents the case where data transfer is not enabled, while CS115 represents the case where the chip select signal **115S** is transferred as the chip select signals **116S** and **117S**.

10   As shown in FIG. **9**, when the external bus **102** and the internal bus **109** are connected to each other by the bus port **110d**, the secret key storing register **107** and the decryption key decryption register **702** cannot be accessed. On the other hand, the chip select signal **116S** is not asserted when the decryption key decryption program **D723b** is executed and the decryption key **D728e** is generated. Accordingly, data under decryption,

15   the secret key, and the decryption key **D728e** are not stored in the internal RAM **104**. Since the chip select signal **117S** is negated when the external bus **102** and the internal bus **109** are connected to each other by the bus port **110d**, data under decryption, the secret key, and the decryption key **D728e** are not outputted to the outside.

A description will be given next to the procedure of decrypting the encrypted

20   program to generate the program **D728a** and executing the program **D728a** with reference to FIG. **10**.

FIG. **10** is a flow chart showing the procedure of decrypting the encrypted program in the fourth embodiment.

First, in Step ST1001, the CPU **103d** transfers the decryption program **D723a** and

25   the encrypted program to the internal RAM **104**.

When the transfer is completed, the whole process advances to Step ST1002 where the CPU **103d** sets the program decryption execute flag **112F** and the RAM copy flag **113F**. At this time, the bus port **110d** disconnects the internal bus **109** and the external bus **102** from each other.

5   After the disconnection, the whole process advances to Step ST1003 where the DMA controller **118d** transfers the decryption program **D723a** and the encrypted program in the internal RAM **104** to the internal RAM **105**.

When the transfer is completed, the whole process advances to Step ST1004 where the CPU **103d** resets the RAM copy flag **113F**. From the resetting of the RAM copy flag **113F** on till the completion of Step ST1006, which will be described later, the CS dispatcher **114d** does not assert the chip select signal **116S**.

10

Then, the whole process advances to Step ST1005 where the CPU **103d** executes the decryption program **D723a** by using the decryption key **D728e**, thereby decrypts the encrypted program, and generates the program **D728a**. The generated program **D728a** is written in the internal RAM **105**.

15

Then, the whole process advances to Step ST1006 where the CPU **103d** executes the program **D728a**.

Finally, the whole process advances to Step ST1007 where the CPU **103d** resets the program decryption execute flag **112F**. When the program decryption execute flag **112F** is reset, the general-purpose register controller **119d** resets the general-purpose registers **120d**. When the program decryption execute flag **112F** is reset, the bus port **110d** connects the internal bus **109** and the external bus **102** to each other. The CS dispatcher **114d** transfers the chip select signal **115S** as the chip select signal **116S** and negates the chip select signal **117S**.

20

25   As shown in FIG. 9, the chip select signal **116S** is not asserted when the

decryption program **D723a** is executed and the program **D728a** is generated. Accordingly, data under decryption, the decryption key **D728e**, and the program **D728a** are not stored in the internal RAM **104**. Since the chip select signal **117S** is negated when the external bus **102** and the internal bus **109** are connected to each other by the bus port **110d**, data under

5   decryption, the decryption key **D728e**, and the program **D728a** are not outputted to the outside.

Thus, it is no more necessary to provide the semiconductor integrated circuit device with an internal nonvolatile memory for keeping the decryption program so that a cost reduction is achieved. Moreover, the encrypted program can be decrypted and

10   executed, while the program and data under decryption are not monitored from the outside. This reduces the probability that the encrypted program is hacked.

In addition, the encryption program and the encryption strength can be selected at the encrypted program transferor.

- Program Delivery Method and System -

15   FIGS. **11** to **17** are views for illustrating a program delivery system and a program delivery method, which will be described herein below by using the present fourth embodiment as an example.

FIGS. **11** to **17** show data transmission and reception between the semiconductor integrated circuit device **701** (corresponding to a second device) within information

20   equipment used by the program user and the PC **128d** (corresponding to a first device) used by the program developer from the encryption of a program till the decryption of the encrypted program.

First, as shown in FIG. **11**, the semiconductor integrated circuit device **701** at the user transfers a public key **D106** stored in the public key storing register **106** to the PC

25   **128d** at the developer.

36

Next, as shown in FIG. 12, the PC **128d** at the developer encrypts the decryption key **D728e** by using the public key **D106** and the decryption key encryption program **D728c** to generate an encrypted decryption key **1201**.

Next, as shown in FIG. 13, the PC **128d** at the developer transfers the encrypted

5   decryption key **1201** to the semiconductor integrated circuit device **701** at the user.

Next, as shown in FIG. 14, the semiconductor integrated circuit device **701** at the user decrypts the encrypted decryption key **1201** by using the secret key **D107** stored in the secret key storing register **107** and the decryption key decryption program **D723b** and stores the decryption key **D728e** in the decryption key storing register **702**.

10   Then, as shown in FIG. 15, the PC **128d** at the developer encrypts the program **D728a** by using the encryption key **D728d** and the encryption program **D728b** to generate an encrypted program **1501**.

Next, as shown in FIG. 16, the PC **128d** at the developer transfers the encrypted program **1501** to the semiconductor integrated circuit device **701** at the user.

15   Finally, as shown in FIG. 17, the semiconductor integrated circuit device **701** at the user decrypts the encrypted program **1501** by using the decryption key **D728e** and the decryption program **D723a** and executes the decrypted program **D728a**.

Thus, the program is encrypted by using the encryption key possessed by the program developer and the encrypted program is delivered to the user. Since the encrypted

20   program can be decrypted by using the decryption key possessed by the program developer, it becomes possible to encrypt the program with an encryption strength desired by the program developer and deliver the encrypted program.

Although each of the first to fourth embodiments has described the case where the control of the internal RAMs **104** and **105** is effected by using the chip select signals in the

25   semiconductor integrated circuit, it will easily be appreciated that the present invention is

also similarly practicable in each of the embodiments even if a write enable signal and a

read enable signal are used.

WHAT IS CLAIMED IS:

1. A semiconductor integrated circuit device comprising:

a first memory for inputting and outputting data between a bus and itself;

a second memory for inputting and outputting data between the bus and itself;

5   a secret key holder for holding a secret key;

a bus port for controlling access from outside to the bus;

a CPU for storing an encrypted program and a decryption program in the first memory via the bus port, decrypting the encrypted program by using the decryption program and the secret key, and executing the decrypted program; and

10   a controller for causing, when the encrypted program and the decryption program are stored in the first memory, the bus port to disable access from the outside, enabling access to the first and second memories, and thereby transferring the encrypted program and the decryption program from the first memory to the second memory,

disabling access to the first memory when the transfer is completed, and

15   disabling access to the second memory when the decryption and the execution of the decrypted program are completed.

2. The semiconductor integrated circuit device of claim 1, further comprising:

a secret key access port for controlling access from the CPU to the secret key holder, wherein

20   the secret key access port enables access to the secret key holder when the transfer is completed and disables access to the secrete key holder when the execution of the decrypted program is completed.

3. The semiconductor integrated circuit device of claim 1, wherein the CPU includes a register and erases data stored in the register if the execution of the decrypted

25   program is completed.

4. The semiconductor integrated circuit device of claim 1, wherein the controller controls access to the first and second memories by controlling chip select signals to the first and second memories.

5. The semiconductor integrated circuit device of claim 1, wherein

5   the controller includes a flag storing portion for storing first and second flags, enables access to the first and second memories when the first flag is set, disables access to the first memory when the first flag is reset and the second flag is set, and disables access to the second memory when each of the first and second flags is reset,

the bus port disables access from the outside when at least one of the first and

10   second flags is set, and

the CPU sets the first and second flags when the encrypted program and the decryption program are inputted to the first memory, resets the first flag when the transfer is completed, and resets the second flag when the execution of the decrypted program is completed.

15   6. A semiconductor integrated circuit device comprising:

a first memory for inputting and outputting data between a bus and itself;

a second memory for inputting and outputting data between the bus and itself;

a first memory port connected between the bus and the first memory to control access from the bus to the first memory;

20   a second memory port connected between the bus and the second memory to control access from the bus to the second memory;

a secret key holder for holding a secret key;

a bus port for controlling access from outside to the bus;

a CPU having a register, the CPU writing an encrypted program and a decryption

25   program in the first memory via the bus port, decrypting the encrypted program by using

the decryption program and the secret key, writing the decrypted program in the second memory, and executing the decrypted program; and

a controller for causing, when the writing to the first memory is completed, the bus port to disable access from the outside to the bus, causing the first memory port to

5   disable the writing to the first memory, and causing the second memory port to enable access to the second memory and

causing, when the execution of the decrypted program is completed, the CPU to erase data stored in the register and disable access to the secrete key holder, while causing the second memory port to disable access to the second memory.

10   7. A semiconductor integrated circuit device comprising:

a first memory for inputting and outputting data between a bus and itself;

a second memory for inputting and outputting data between the bus and itself;

a memory port connected between the bus and the first memory to control access from the bus to the first memory;

15   a secret key holder for holding a secret key;

a bus port for controlling access from outside to the bus;

a CPU having a register, the CPU writing an encrypted program and a decryption program in the first memory via the bus port, decrypting the encrypted program by using the decryption program and the secret key, writing the decrypted program in the second

20   memory, and executing the decrypted program; and

a controller including a memory initializer for erasing data in the second memory, the controller causing, when the wiring to the first memory is completed, the bus port to disable access from the outside to the bus and causing the memory port to disable the writing to the first memory and

25   causing, when the execution of the decrypted program is completed, the CPU to

41

erase data stored in the register and disable access to the secret key holder and causing the

memory initializer to erase the data in the second memory.

8. A semiconductor integrated circuit device comprising:

a first memory for inputting and outputting data between a bus and itself;

5   a second memory for inputting and outputting data between the bus and itself;

a secret key holder for holding a secret key;

a decryption key holder for holding a decryption key;

a bus port for controlling access from outside to the bus;

a CPU including a register, the CPU performing first storage for storing the

10   encrypted decryption key and a decryption key decryption program in the first memory via

the bus port, performing first decryption for decrypting the encrypted decryption key by

using the decryption key decryption program and the secret key, writing the decrypted

decryption key in the decryption key holder, performing second storage for storing an

encrypted program and a decryption program in the first memory, performing decryption

15   for decrypting the encrypted program by using the decryption program and the decrypted

decryption key, and executing the decrypted program; and

a controller for causing, when the first storage to the first memory is completed,

the bus port to disable access from the outside to the bus and enabling access to the first

and second memories such that the encrypted decryption key and the decryption key

20   decryption program are transferred from the first memory to the second memory,

enabling, when the transfer is completed, access to the secret key holder and

disabling access to the first memory;

causing, when the first decryption is completed, the CPU to erase data stored in

register and disable access to the secret key holder, while disabling access to the second

25   memory, enabling access to the first memory, and causing the bus port to enable access

42

from the outside to the bus,

causing, when the second storage to the first memory is completed, the bus port to

disable access from the outside to the bus and enabling access to the second memory such

that the encrypted program and the decryption program are transferred from the first

5   memory to the second memory,

enabling, when the transfer is completed, access to the decryption key holder and

disabling access to the first memory, and

causing, when the second decryption and the execution of the decrypted program

are completed, the CPU to erase data stored in the register and disable access to the secret

10   key holder and disabling access to the second memory.

9. A program delivery method for delivering a program between a first device and

a second device, the method comprising the steps of:

transferring a public key from the second device to the first device;

transferring a decryption program to the second device from the outside thereof;

15   encrypting the program by using the public key in the first device and transferring

the encrypted program to the second device; and

decrypting the encrypted program by using a secret key corresponding to the

public key and the decryption program in the second device.

10. A program delivery method for delivering a program between a first device

20   and a second device, the method comprising the steps of:

transferring a public key from the second device to the first device;

encrypting a decryption key by using the public key in the first device and

transferring the encrypted decryption key to the second device;

decrypting the encrypted decryption key by using a secret key corresponding to

25   the public key in the second device;

43

encrypting the program by using an encryption key corresponding to the decryption key in the first device and transferring the encrypted program to the second device; and

decrypting the encrypted program by using the decrypted decryption key in the

5 second device.

11. A program delivery system for delivering a program, the system comprising:

a first device and a second device,

the first device encrypting the program by using a public key and transferring the encrypted program to the second device and

10   the second device decrypting the program encrypted by the first device by using a secret key corresponding to the public key and a decryption program transferred from the outside of the second device.

12. A program delivery system for delivering a program, the system comprising:

a first device and a second device,

15   the first device encrypting a decryption key by using a public key, transferring the encrypted decryption key to the second device, encrypting the program by using an encryption key corresponding to the decryption key, and transferring the encrypted program to the second device,

the second device decrypting the decryption key encrypted by the first device by

20 using a secret key corresponding to the public key and decrypting the program encrypted by the first device by using the decrypted decryption key.

ABSTRACT OF THE DISCLOSURE

When an encrypted program and a decryption program are inputted to a first memory, a semiconductor integrated circuit device causes a bus port to disable access from the outside and enables access to the first memory and to a second memory, thereby

5 transferring the encrypted program and the decryption program from the first memory to the second memory. When the transfer is completed, the semiconductor integrated circuit device disables access to the first memory and gives, to a CPU, an instruction to decrypt the encrypted program by using a secret key held in a secret key holder and the decryption program and execute the decrypted program. After the execution of the decrypted program

10 is completed, the semiconductor integrated circuit device disables access to the second memory.
